AB A method for identifying analytes which directly or indirectly affect ***tryptophan*** ***hydroxylase*** ***isoform*** 2 (***TPH2***) expression is described. The method enables glucocorticoid receptor modulators and &bgr;-hydroxysteroid dehydrogenase type 1 (&bgr;-HSD1) inhibitors to be screened for central nervous system penetrance and activity by determining their ability to regulate expression of ***TPH2*** . The method is particularly useful for identifying analytes which suppress glucocorticoid disruption of central serotonergic neurotransmission in the brain.

AB Recently, a second gene that codes for the rate-limiting enzyme in serotonin synthesis was found in brain, named tryptophan hydroxylase-2 (TPH-2). We sequenced overlapping segments (251 and 510 bp) of 5' monkey TPH-2 and questioned whether TPH-2 is regulated by estrogen (E) and progesterone (P) in serotonin neurons of macaques. Monkey TPH-2 was 97% homologous to human TPH-2 and 65% homologous to monkey TPH-1 in the coding region. Spayed monkeys were administered placebo, E-only, P-only, or E + P for 1 mo via Silastic implants (n = 4/treatment) and the midbrain was utilized for TPH-2 in situ hybridization (ISH). Addnl. monkeys (n = 3/treatment) were used to det. the relative abundance of TPH-2 mRNA with quant. (q) RT-PCR. In the ISH assay, all of the hormone treatments caused a significant and similar increase in TPH-2 mRNA optical d. (fourfold; P < 0.004) and pos. pixel area (twofold; P < 0.002) over spayed controls. Treatment with E or E + P for 1 mo increased the relative abundance of TPH-2 mRNA over spayed controls in the qRT-PCR assay (ANOVA P < 0.05 and P < 0.007, resp.). In conclusion, ovarian steroids stimulate TPH-2 mRNA expression, which could in turn cause an increase in serotonin synthesis. This would impact many of the neural functions that are governed by serotonin.

AB Background: Recently a novel ***tryptophan*** ***hydroxylase*** ***isoform*** (***TPH2***) was identified and shown to be highly expressed in the central nervous system (CNS). Hormonal effects on ***TPH2*** mRNA expression in the rodent dorsal raphe nucleus (DRN) are unknown. Methods: In situ hybridization histochem. and real-time reverse transcriptase-polymerase chain reaction (RT-PCR) were used to assess the effects of dexamethasone or estradiol on ***TPH2*** mRNA levels in the DRN of C57/Bl6 mice. Results: Dexamethasone reduced ***TPH2*** mRNA levels in the DRN of both ovx female and intact male mice. Redn. of ***TPH2*** mRNA in the DRN was blocked by co-administration of mifepristone. Estradiol had no detectable effect on ***TPH2*** mRNA levels in the DRN. Conclusions: ***TPH2*** mRNA is regulated by glucocorticoids but not estradiol in the mouse DRN. Glucocorticoid- mediated redn. of ***TPH2*** message may have relevance to the etiol. of major depression, psychotic major depression in particular, where elevated glucocorticoids are one hallmark of the disease.

AB Most of the candidate gene studies in bipolar disorder have focused on the major neurotransmitter systems that are influenced by drugs used in the treatment of this disorder. The monoamine oxidase A (MAOA) and the tryptophan hydroxylase (TPH1, ***TPH2***) genes are two of the candidates that have been tested in a series of assocn. studies using unrelated or family-based controls. This review summarizes the existing assocn. studies regarding these genes. Most of these studies were based on the unrelated case-control design with samples of 50 to 600 subjects. Regarding MAOA, three meta-analyses with partially overlapping samples supported a modest effect of this gene in bipolar disorder in female Caucasians. However, as several studies could not replicate these findings, more work is necessary to demonstrate unequivocally the involvement of MAOA in bipolar disorder and establish the biol. mechanism underlying the genetic assocn. With respect to TPH1 and ***TPH2*** , the majority of studies did not provide evidence for an assocn. between these genes and bipolar disorder. The genes are more likely to be related to suicidal behavior than to bipolar disorder.

AB Tryptophan hydroxylase (TPH) catalyzes the rate-limiting reaction in the biosynthesis of serotonin. In humans, two different TPH genes exist, located on chromosomes 11 and 12, resp., and encoding two enzymes (TPH1 and ***TPH2***) with an overall sequence identity of 71%. The authors have expressed both enzymes as various fusion proteins in Escherichia coli and using an in vitro transcription/translation system, and compared their soly. and kinetic properties. ***TPH2*** is more sol. than TPH1, has a higher mol. wt. and different kinetic properties, including a lower catalytic efficiency towards phenylalanine than TPH1. Both enzymes are phosphorylated by cAMP-dependent protein kinase A. ***TPH2*** was phosphorylated at Ser-19, a phosphorylation site not present in TPH1. The differences between TPH1 and ***TPH2*** have important implications for the regulation of serotonin prodn. in the brain and the periphery and may provide an explanation for some of the diverging results reported for TPH from different sources in the past.

AB Tryptophan hydroxylase (TPH), being the rate-limiting enzyme in the biosynthesis of serotonin plays a major role as candidate gene in several psychiatric disorders. Recently, a second TPH isoform (***TPH2***) was identified in mice, which was exclusively present in the brain. In a previous post-mortem study of our own group, we could demonstrate that ***TPH2*** is also expressed in the human brain, but not in peripheral tissues. This is the first report of an assocn. study between polymorphisms in the ***TPH2*** gene and major depression (MD). We performed single-nucleotide polymorphism (SNP), haplotype and linkage disequil. studies on 300 depressed patients and 265 healthy controls with 10 SNPs in the ***TPH2*** gene. Significant assocn. was detected between one SNP (P=0.0012, global P=0.0051) and MD. Haplotype anal. produced addnl. support for assocn. (P<0.0001, global P=0.0001). Our findings provide evidence for an involvement of genetic variants of the ***TPH2*** gene in the pathogenesis of MD and might be a hint on the repeatedly discussed duality of the serotonergic system. These results may open up new research strategies for the anal. of the obsd. disturbances in the serotonergic system in patients suffering from several other psychiatric disorders.

AB Trp hydroxylase, the rate-limiting enzyme in the biosynthesis of serotonin, represents a major candidate in numerous genetic assocn. analyses of suicidal behavior; however, the results are so far inconclusive. Recently, a second Trp hydroxylase isoform (***TPH2***) was identified in mice, which was exclusively present in the brain. In a previous postmortem study of our own group, the authors could demonstrate that ***TPH2*** is also expressed in the human brain but not in peripheral tissues. We performed single nucleotide polymorphisms, haplotypes, and linkage disequil. studies on 263 suicide victims and 266 healthy control subjects with 10 single nucleotide polymorphisms in the ***TPH2*** gene. Significant assocn. was detected between one single nucleotide polymorphism (p = .004, global p = .01) and suicide. Addnl., haplotype anal. also produced support for assocn. (p < .0001, global p = .0001). This is the first report about an assocn. between ***TPH2*** gene polymorphisms and completed suicide. These findings provide evidence for an involvement of genetic variants in the ***TPH2*** gene in suicidal behavior. These results might open up new research strategies for the anal. of the obsd. disturbances in the serotonergic system in several other psychiatric disorders.

AB The putative role of the tryptophan hydroxylase 2 (***TPH2***) gene in suicide attempters was studied using a large and well-characterized sample of patients with bipolar disorder. The study population consisted of 336 bipolar patients from 305 families who were recruited in the Toronto area. Among the bipolar patients, 267 patients had history of suicide ideas or attempt. The genotypes of ***TPH2*** hCV245410, hCV8376173, and rs1487280 polymorphisms were detd. by Taqman assay. Allelic and haplotype transmission tests in suicide attempters were performed using TDT and TRANSMIT. When the suicide behavior was analyzed as a quant. trait by the family based assocn. test, no significant differences were found for the three polymorphisms. All the eight possible haplotypes showed no significant results when weighted on the suicide behavior as the quant. trait. In bipolar patients, the TDT did not show significant bias for hCV245410, hCV8376173, and rs1487280.

AB In this study, we sought out to test the hypothesis that genetic factors may influence antidepressant response to fluoxetine. The investigation focused on seven candidate genes in the serotonergic pathway involved in the synthesis, transport, recognition, and degrdn. of serotonin. Our din. sample consisted of 96 subjects with unipolar major depression treated with fluoxetine with response variables assessed after a 12-wk trial. Patient data were also collected to investigate the pattern of drug response. Using a high-throughput single-nucleotide polymorphism (SNP) genotyping platform and capillary electrophoresis, we genotyped patients at 110 SNPs and four repeat polymorphisms located in seven candidate genes (HTR1A, HTR2A, HTR2C, MAOA, SLC6A4, TPH1, and ***TPH2***). Statistical tests performed included single-locus and haplotype assocn. tests, and linkage disequil. (LD) estn. Little evidence of population stratification was obsd. in the sample with 20 random SNPs using a genomic control procedure. Our most intriguing result involved three SNPs in the TPH1 gene and one SNP in the SLC6A4 gene, which show significant single-locus assocn. when response to fluoxetine is compared to nonresponse (P= 0.02-0.04). All odds ratios indicated an increased risk of not responding to fluoxetine. In the specific response vs nonspecific and nonresponse comparison, three SNPs in the ***TPH2*** gene (P= 0.02-0.04) were pos. assocd. and one SNP in the HTR2A gene (P= 0.02) was neg. assocd. When comparing specific response to nonspecific response, we found significant neg. assocns. in three SNPs in the HTR2A gene (P= 0.001-0.03) and two SNPs in the MAOA gene (P= 0.03-0.05). We obsd. variable, although strong LD, in each gene and unexpectedly low nos. of estd. haplotypes, formed from tagged SNPs. Significant haplotype assocns. were found in all but the HTR1A and HTR2C genes. Although these data should be interpreted cautiously due to the small sample size, these results implicate TPH1 and SLC6A4 in general response, and HTR2A, ***TPH2*** , and MAOA in the specificity of response to fluoxetine. Intriguingly, we observe that a no. of the less frequent alleles of many of the SNP markers were assocd. with the nonresponse and nonspecific phenotypes.

AB Pharmacol. and challenge study data showed an involvement of the serotonergic system in the development of obsessive-compulsive disorder (OCD). We studied transmission disequil. of polymorphisms in three candidate genes of the serotonergic pathway in 64 trios comprising patients with early onset OCD and both of their parents. Polymorphisms of the following genes were studied; tryptophan hydroxylase 1 (rs1800532), serotonin transporter (polymorphism in the promoter region; 5-HTTLPR) and the serotonin 1 B receptor (rs6296). This is, to our knowledge, one of the first family based assocn. studies pertaining to children and adolescents with OCD. We did not detect transmission disequil. of the investigated polymorphisms in OCD. Hence, these polymorphisms do not play a major role in the genetic predisposition to early onset OCD.

AB Tryptophan hydroxylase is the first of four enzymes in the melatonin biosynthetic pathway. Recent studies have shown that there are two genes, Tph1 and ***Tph2*** , that encode tryptophan hydroxylase in mammals. In this study, we investigated which of the two genes is expressed in the rat retina. To that end, we measured Tph1 (classical Tph) and ***Tph2*** mRNA levels using real-time quant. RT-PCR in the retina. Our data demonstrate that Tph1 mRNA is the prevalent form expressed in the retina; ***Tph2*** mRNA is also present but the level is very low. We also measured Tph1 expression levels in the outer nuclear layer, inner nuclear layer, and ganglion cell layer by combining laser capture microdissection and real-time RT-PCR. Tph1 mRNA is more abundant in the photoreceptors of the outer nuclear layer than in the inner nuclear layer or ganglion cell layer. Tph1 and ***Tph2*** transcripts showed robust diurnal rhythms of abundance, with highest levels at night. Our results support the hypothesis that Tph1 is involved in melatonin synthesis in retinal photoreceptor cells.

AB Serotonin (5-HT) controls a wide range of biol. functions. In the brain, its implication as a neurotransmitter and in the control of behavioral traits has been largely documented. At the periphery, its modulatory role in physiol. processes, such as the cardiovascular function, is still poorly understood. The rate limiting enzyme of 5-HT synthesis, tryptophan hydroxylase (TPH), is encoded by two genes: the well characterized TPH1 gene and a recently identified ***TPH2*** gene. Based on the study of a mutant mouse in which the TPH1 gene has been inactivated by replacement of the .beta.-galactosidase gene, we established that the neuronal ***TPH2*** is expressed in neurons of the raphe nuclei and of the myenteric plexus, whereas the non-neuronal TPH1, as detected by .beta.-galactosidase expression, is expressed in the pineal gland and the enterochromaffin cells. Anat. examn. of the mutant mice revealed larger heart sizes as compared to wild-type. Histol. investigations indicated that the primary structure of the heart muscle is not affected. Hemodynamic analyses in mutant animals demonstrated abnormal cardiac activity which ultimately leads to heart failure. This is the first report linking loss of TPH1 gene expression, and thus of peripheral 5-HT, to a cardiac dysfunction phenotype. The TPH1-/- mutant may be a valuable model for investigating cardiovascular dysfunction such as those obsd. in human heart failure.

AB Tryptophan hydroxylase (TPH) as rate limiting enzyme in the biosynthesis of serotonin plays a major role as candidate gene in several psychiatric disorders. Recently a second TPH isoform (***TPH2***) was identified in mice, which was exclusively expressed in the brain. We investigated whether the mRNA of the human homolog of this new ***TPH2*** isoform is expressed in the human brain but not in peripheral tissues. The study was performed with postmortem specimen obtained from two subjects who died on cardiovascular failure. ***TPH2*** mRNA levels were detd. by quant. real time RT-PCR. ***TPH2*** mRNA was exclusively present in the human brains but not in the investigated peripheral tissues. Our finding may open up new research strategies for the anal. of the repeatedly obsd. disturbances in the serotonergic system in patients suffering from several psychiatric disorders.

AB Mammary gland development is controlled by a dynamic interplay between endocrine hormones and locally produced factors. Biogenic monoamines (serotonin, dopamine, norepinephrine, and others) are an important class of bioregulatory mols. that have not been shown to participate in mammary development. Mammary glands stimulated by prolactin (PRL) express genes essential for serotonin biosynthesis (tryptophan hydroxylase [TPH] and arom. amine decarboxylase). TPH mRNA was elevated during pregnancy and lactation, and serotonin was detected in the mammary epithelium and in milk. TPH was induced by PRL in mammosphere cultures and by milk stasis in nursing dams, suggesting that the gene is controlled by milk filling in the alveoli. Serotonin suppressed .beta.-casein gene expression and caused shrinkage of mammary alveoli. Conversely, TPH1 gene disruption or antiserotonergic drugs resulted in enhanced secretory features and alveolar dilation. Thus, autocrine-paracrine serotonin signaling is an important regulator of mammary homeostasis and early involution.

AB Background: Regulation of raphe serotonergic cells is fundamental to the prevailing hypothesis of major depression pathophysiol. Tryptophan hydroxylase (TPH) is the rate-limiting enzyme in serotonin biosynthesis, but brainstem TPH mRNA expression has been difficult to measure and study. Recently, a novel paralog of TPH, ***TPH2*** (or neuronal TPH), was described, but its anat. expression is unknown. Methods: An in situ hybridization histochem. survey was conducted across Sprague-Dawley rat brain for TPH1 and ***TPH2*** mRNA. Semiquant. techniques were used to est. relative mRNA levels in individual cells. Results: Almost exclusively, ***TPH2*** mRNA is expressed in raphe, in a pattern overlapping the histol. defined raphe nuclei. In sharp contrast, TPH1 (the previously known TPH) is expressed predominantly in pineal gland. There is no appreciable overlap in the expression of these paralogs. The level of ***TPH2*** mRNA expression in individual raphe cells is approx. 2.5-fold greater than the level of TPH1 expression in pinealocytes. Conclusions: ***TPH2*** mRNA has an anat. expression pattern consistent with brainstem raphe nuclei and is likely to be the gene giving rise to the majority of TPH activity in these cells. The robust expression of ***TPH2*** in brainstem should facilitate studies on the transcriptional regulation of raphe serotonin biosynthesis.

AB A review. Serotonin (5-hydroxytryptophan, 5-HT) is a neurotransmitter synthesized in the raphe nuclei of the brain stem and involved in the central control of food intake, sleep, and mood. Accordingly, dysfunction of the serotonin system has been implicated in the pathogenesis of psychiatric diseases. At the same time, serotonin is a peripheral hormone produced mainly by enterochromaffin cells in the intestine and stored in platelets, where it is involved in vasoconstriction, hemostasis, and the control of immune responses. Moreover, serotonin is a precursor for melatonin and is therefore synthesized in high amts. in the pineal gland. Tryptophan hydroxylase (TPH) catalyzes the rate limiting step in 5-HT synthesis. Until recently, only one gene encoding TPH was described for vertebrates. By gene targeting, we functionally ablated this gene in mice. To our surprise, the resulting animals, although being deficient for serotonin in the periphery and in the pineal gland, exhibited close to normal levels of 5-HT in the brain stem. This led us to the detection of a second TPH gene in the genome of humans, mice, and rats, called ***TPH2***. This gene is predominantly expressed in the brain stem, while the classical TPH gene, now called TPH1, is expressed in the gut, pineal gland, spleen, and thymus. These findings clarify puzzling data, which have been collected over the last decades about partially purified TPH proteins with different characteristics and justify a new concept of the serotonin system. In fact, there are two serotonin systems in vertebrates, independently regulated and with distinct functions.

AB A second gene encoding a functional tryptophan hydroxylase activity has recently been described (***TPH2***), which is expressed abundantly in brainstem, the primary site of serotonergic neurons in the CNS. As serotonin (5-HT) has an important role as a precursor of the nocturnal synthesis of the pineal gland hormone, melatonin, it was of interest to det. the relative expression of TPH1 and 2 mRNA in the rat pineal during the light:dark (L:D) cycle using sensitive real-time RT-PCR assays which were developed for each TPH isoform. TPH1 mRNA expression was 105-fold more abundant in rat pineal than ***TPH2*** , and showed a significant .apprx.4-fold nocturnal increase in expression which may contribute to the previously described nocturnal increase in pineal tryptophan hydroxylase activity. ***TPH2*** expression within the gland showed no significant variation with time of day and was very low (.apprx.300 copies/gland) indicating expression in the small proportion of "non-pinealocyte" cells in the gland.

AB A review describes the identification of two tryptophan hydroxylase (TPH) mRNA species arising from different promoters and having different translational efficiency. The expression of more efficiently translated isoform is increased in response to stress. The study by Walther et al. (2003) demonstrated that a Tph1 knockout mouse failed to generate the expected phenotype, in which Tph1-deficient mice continued to produce 5-hydroxytryptamine in the brain, but had almost no detectable serotonin in the duodenum, and none in the whole blood. The study found that the antibodies commonly used to identify TPH cross-reacted to both Tph1 and ***Tph2*** gene products.

AB Serotonin (5-HT) is synthesized in two steps, with tryptophan hydroxylase (TPH) as the rate-limiting enzyme. To study the physiol. impact of the loss of 5-HT synthesis, the authors generated mice genetically deficient for TPH (Tph-1-). Tph-/- mice expressed normal amts. of 5-HT in classical serotonergic brain regions. However, Tph-/- mice lacked 5-HT in the periphery except for in the duodenum. Tph-/- mice exhibited no significant behavioral differences in elevated plus maze and hole board tests, which are indicative for 5-HT related behavior. Despite suggestions of a possible second TPH isoform mol. verification has been lacking. The authors therefore cloned and sequenced the TPH isoform (referred as ***Tph2***) (GenBank: AY090565) which was different from the known TPH (referred to as Tph1), Pah and Th of the mouse. Tph1 mRNA was detected in the duodenum, but not in the brain. In contract ***Tph2*** was detected exclusively in the brain. In addn. the authors also cloned and sequenced the rat and human ***TPH2*** homologs (GenBank: AY098915 and AY098914). The discovered duality of the serotonin system in vertebrates may open up new avenues for specific therapeutic approaches exclusively affecting central or peripheral 5-HT actions.

AB Novel vanadyl (VO2+) chloro and hydroxo complexes with the hindered TpPri2 (hydrotris(3,5-diisopropyl-1-pyrazolyl)borate) and TpMe2 (hydrotris(3,5-dimethylpyrazolyl-1-pyrazolyl)borate) ligands were prepd. and structurally characterized successfully. Ligand displacement of VOCl2(MeCN)2(H2O) by TpR afforded octahedral chloro complexes, TpRV(O)(Cl)(X) (1: R = Pri2, X = PzPri2H; 2: R = Pri2, X = py; 6: R = Me2, X = NCMe). Hydrolysis of the obtained chloro complexes yielded the corresponding hydroxo complexes 4, 5, and 7, but their structures were very unique and different from that of the previously reported dinuclear VO2+ bis(.mu.-hydroxo) complex with the less hindered ***TpPri2*** (hydrotris(1-pyrazolyl)borate) ligand. For the TpPri2 complexes, the octahedral hydroxo-aqua complex, TpPri2V(O)(OH)(OH2) (4), and the trinuclear bis(.mu.-hydroxo)bis(.mu.-pyrazolato) complex, TpPri2V(O)(.mu.-OH)(.mu.-PzPri2)V(O)(.mu.-OH)(.mu.-PzPri2)V(O)TpPri2 (5), were isolated. The hydroxo-aqua complex 4 was dimerized through the intermol. hydrogen-bonding interaction between the hydroxo and aqua ligands forming the H3O2- bridging ligand. The trinuclear complex 5 consisted of two octahedral TpPri2V(O) fragments and a distorted trigonal-bipyramidal non-TpPri2-supported VO2+ center, sitting on the pseudo C2 symmetry axis, and was formed via coupling of 4 and the VO2+-pyrazolato species, resulting from partial decompn. of the chloro complexes during the hydrolysis. Steric repulsion of the bulky Pri groups in TpPri2 might hinder the formation of a dinuclear bis(.mu.-

hydroxo) complex like the ***TpH2*** and TpMe2 derivs. The dinuclear bis(.mu.-hydroxo) complex with the TpMe2 ligand, (.kappa.3-TpMe2)V(O)(.mu.-OH)2V(O)(.kappa.2-TpMe2) (7), consisted of syn-arranged V:O fragments, having the different coordination geometries of the vanadium centers (octahedron with .kappa.3-TpMe2 and trigonal bipyramid with .kappa.2-TpMe2). Intramol. hydrogen-bonding interaction between one of the two hydroxo groups and the noncoordinated pyrazolyl nitrogen atom in .kappa.2-TpMe2 was obsd.

AB The variability of seed tocopherol content in wild sunflower species, the expressivity of tph1 and ***tph2*** mutations in different lines and the oxidative stability of sunflower oil with altered tocopherol and fatty acid compn. were objectives of this research. Near-isogenic lines for three genes, i.e. Tph1, ***Tph2***, and Ol, were developed and investigated. Tocopherol content was detd. with TLC and HPLC, as well as fatty acid compn. with GC of Me esters. Rancimat tests were used to est. the oxidative stability of the oil. The seed tocopherol compn. of wild sunflower species was shown to be uniform with a prevailing content of the .alpha.-homolog (90-99%). The genetic background of different near-isogenic lines was found to influence expressivity of mutations for tocopherol compn. High content of strong antioxidants, such as .beta.-, .gamma.-, and .delta.-tocopherols increased oil oxidative stability of linoleic and oleic types of oil by 1.2-3.0 times. The breeding model of sunflower hybrids should include antioxidant and vitamin parameters balanced for oils of different applications.

AB A structural study of the products of the reaction of R3Sn(IV) derivs. (R = Me, Bu, Ph) with 6-thiopurine, 6-***TPH2*** , and its sodium salt, 6-TPHNa, has been undertaken using Moessbauer spectroscopy and the point-charge model rationalization of the Moessbauer parameter nuclear quadrupole splitting. The synthetic reactions have been carried out at .apprx.0, 20, and 50.degree.. The Moessbauer spectra of the complexes R3Sn(6-TPH) are consistent with the occurrence of two distinct tin(IV) sites in samples prepd. at the lower temp., while one only site appears by increasing the temp. of the reaction. Two tin sites constantly occur in the products of the reactions involving the Ph3Sn(IV) moiety; the stoichiometry is assumed to be (Ph3Sn)3(6-TPH)(6-TP) for the uniquely formed complex. Solid state polymeric structures with trigonal bipyramidal environments of the tin atoms and planar SnC3 skeletons have been proposed. The apical ligand atoms have been assumed to be N, S and N, N in the samples showing two individual tin(IV) sites, and N, N when a single site was present.
